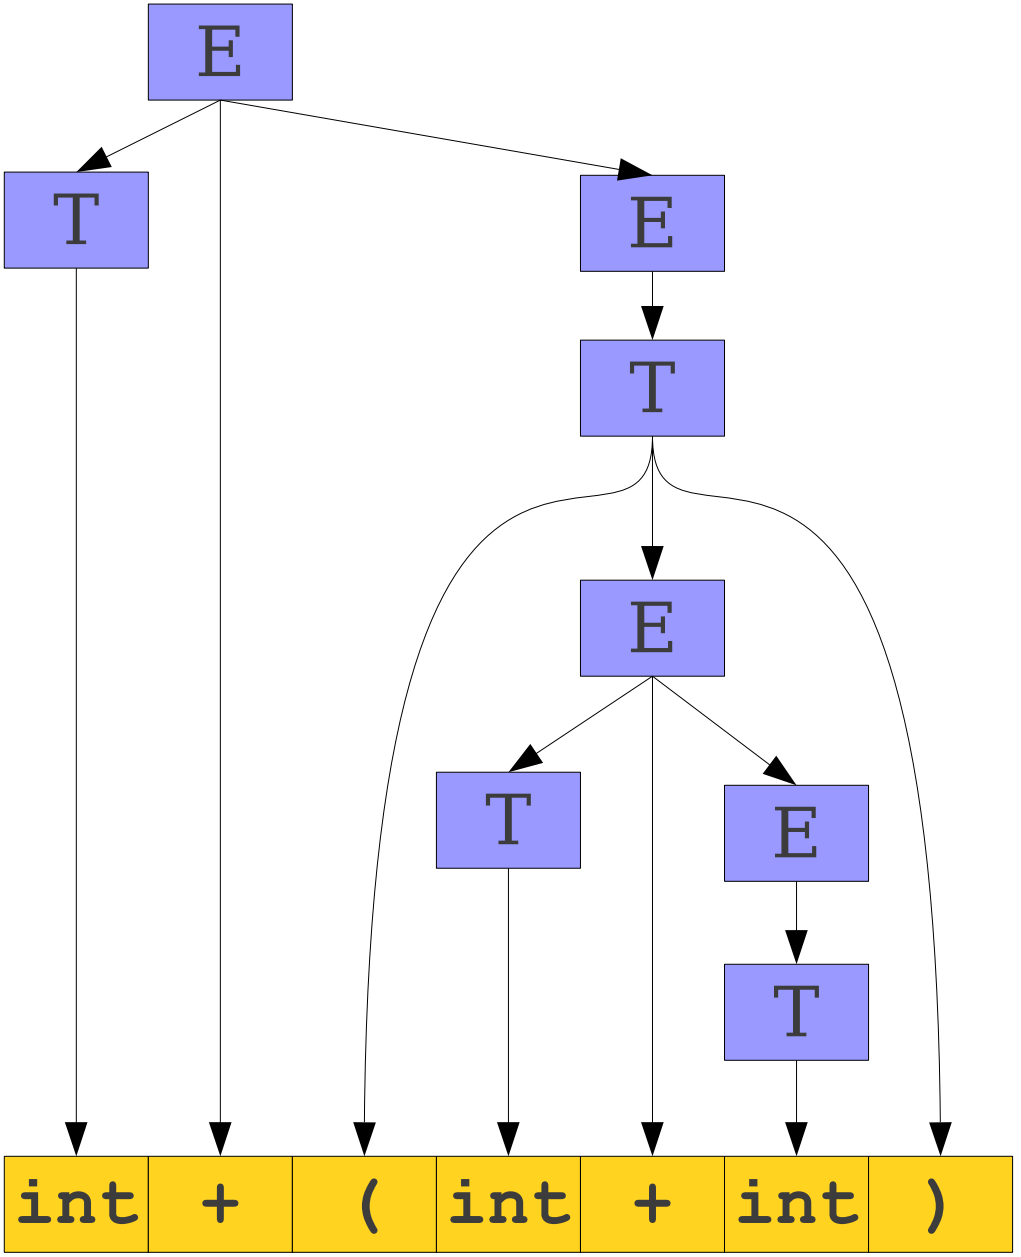
Top-Down Parsing

E → T
E → T + E
T → int
T → (E)



LL(1) Parse Tables

E → **`int`**
E → **`(`E Op E`)`**
Op → **`+`**
Op → **`*`**

	`int`	`(`	`)`	`+`	`*`
E	`int`	`(`E Op E`)`			
Op				`+`	`*`

FIRST Sets

- We want to tell if a particular nonterminal **A** derives a string starting with a particular nonterminal **t**.
- We can formalize this with **FIRST sets**.

$$\text{FIRST}(\mathbf{A}) = \{\ \mathbf{t} \mid \mathbf{A} \Rightarrow^* \mathbf{t}\omega \text{ for some } \omega\ \}$$

- We also include **ε** in FIRST(**A**) if A can produce the empty string.
- Intuitively, FIRST(**A**) is the set of terminals that can be at the start of a string produced by **A**.
- We can generalize FIRST to strings with FIRST*(*ω*) being the set of all terminals (or **ε**) that can appear at the start of a string derived from *ω*.

FIRST Computation with ε

- Initially, for all nonterminals **A**, set

  FIRST(**A**) = { **t** | **A** → **t**ω for some ω }

- For all nonterminals **A** where **A** → **ε** is a production, add **ε** to FIRST(**A**).
- Repeat the following until no changes occur:
  - For each production **A** → α, set FIRST(**A**) = FIRST(**A**) ∪ FIRST*(α)

FOLLOW Sets

- With ε-productions in the grammar, we may have to "look past" the current nonterminal to what can come after it.
- The **FOLLOW set** represents the set of terminals that might come after a given nonterminal.
- Formally:

$$\text{FOLLOW}(\mathbf{A}) = \{\ \mathtt{t} \mid \mathbf{S} \Rightarrow^* \boldsymbol{\alpha}\mathbf{A}\mathtt{t}\boldsymbol{\omega} \text{ for some } \boldsymbol{\alpha}, \boldsymbol{\omega}\ \}$$

  where **S** is the start symbol of the grammar.
- Informally, every nonterminal that can ever come after **A** in a derivation.

Computation of FOLLOW Sets

- Initially, for each nonterminal **A**, set

  FOLLOW(**A**) = { **t** | **B** → ***α*****A****t*****ω*** is a production }

- Add **$** to FOLLOW(**S**), where **S** is the start symbol.
- Repeat the following until no changes occur:
  - If **B** → ***α*****A*****ω*** is a production, set FOLLOW(**A**) = FOLLOW(**A**) ∪ FIRST*(***ω***) - { **ε** }.
  - If **B** → ***α*****A*****ω*** is a production and **ε** ∈ FIRST*(***ω***), set FOLLOW(**A**) = FOLLOW(**A**) ∪ FOLLOW(**B**).

The Final LL(1) Table Algorithm

- Compute FIRST(**A**) and FOLLOW(**A**) for all nonterminals **A**.
- For each rule **A** → ω, for each terminal **t** ∈ FIRST*(ω), set T[**A**, **t**] = ω.
  - Note that **ε** is not a terminal.
- For each rule **A** → ω, if **ε** ∈ FIRST*(ω), set T[**A**, **t**] = ω for each **t** ∈ FOLLOW(**A**).

An Egregious Abuse of Notation

- Compute FIRST(**A**) and FOLLOW(**A**) for all nonterminals **A**.
- For each rule **A** → ω, for each terminal `t` ∈ FIRST*(ωFOLLOW(**A**)), set T[**A**, `t`] = ω.

Example LL(1) Construction

The Limits of LL(1)

A Grammar that is Not LL(1)

- Consider the following (left-recursive) grammar:

  A → **A**`b` | `c`

- FIRST(**A**) = {`c`}
- However, we cannot build an LL(1) parse table.
- **Why?**

A Grammar that is Not LL(1)

- Consider the following (left-recursive) grammar:

  A → **A**`b` | `c`

- FIRST(**A**) = {`c`}
- However, we cannot build an LL(1) parse table.
- **Why?**

	b	c
A		**A** → **A**`b` **A** → `c`

A Grammar that is Not LL(1)

- Consider the following (left-recursive) grammar:

  A → **A**`b` | `c`

- FIRST(**A**) = {`c`}
- However, we cannot build an LL(1) parse table.
- **Why?**

	b	c
A		**A** → **A**`b` **A** → `c`

- **Cannot uniquely predict production!**
- This is called a **FIRST/FIRST conflict**.

Eliminating Left Recursion

- In general, left recursion can be converted into **right recursion** by a mechanical transformation.
- Consider the grammar

$$\mathbf{A} \rightarrow \mathbf{A}\boldsymbol{\omega} \mid \boldsymbol{\alpha}$$

- This will produce $\boldsymbol{\alpha}$ followed by some number of $\boldsymbol{\omega}$'s.
- Can rewrite the grammar as

$$\mathbf{A} \rightarrow \boldsymbol{\alpha}\mathbf{B}$$

$$\mathbf{B} \rightarrow \boldsymbol{\varepsilon} \mid \boldsymbol{\omega}\mathbf{B}$$

Another Non-LL(1) Grammar

- Consider the following grammar:

  E → **T**

  E → **T** `+` **E**

  T → `int`

  T → `(` **E** `)`

- FIRST(**E**) = { `int`, `(` }
- FIRST(**T**) = { `int`, `(` }
- Why is this grammar not LL(1)?

Another Non-LL(1) Grammar

- Consider the following grammar:

  E → **T**

  E → **T** + **E**

  T → `int`

  T → (**E**)

- FIRST(**E**) = { `int`, `(` }
- FIRST(**T**) = { `int`, `(` }
- Why is this grammar not LL(1)?

A Formal Characterization of LL(1)

- A grammar G is LL(1) iff for any productions $\mathbf{A} \rightarrow \boldsymbol{\omega}_1$ and $\mathbf{A} \rightarrow \boldsymbol{\omega}_2$, the sets

  $$\text{FIRST}(\boldsymbol{\omega}_1\ \text{FOLLOW}(\mathbf{A}))$$

  and

  $$\text{FIRST}(\boldsymbol{\omega}_2\ \text{FOLLOW}(\mathbf{A}))$$

  are disjoint.
- This condition is equivalent to saying that there are no conflicts in the table.

The Strengths of LL(1)

LL(1) is Straightforward

- Can be implemented quickly with a table-driven design.
- Can be implemented by **recursive descent**:
  - Define a function for each nonterminal.
  - Have these functions call each other based on the lookahead token.

LL(1) is Fast

- Both table-driven LL(1) and recursive-descent-powered LL(1) are fast.
- Can parse in O(n $|G|$) time, where n is the length of the string and $|G|$ is the size of the grammar.

Summary

- **Top-down parsing** tries to derive the user's program from the start symbol.
- **Leftmost BFS** is one approach to top-down parsing; it is mostly of theoretical interest.
- **Leftmost DFS** is another approach to top-down parsing that is uncommon in practice.
- **LL(1)** parsing scans from left-to-right, using one token of lookahead to find a leftmost derivation.
- **FIRST sets** contain terminals that may be the first symbol of a production.
- **FOLLOW sets** contain terminals that may follow a nonterminal in a production.
- **Left recursion** and **left factorability** cause LL(1) to fail and can be mechanically eliminated in some cases.
